

First, I decompiled the .pyc using pylingual.io and got to see an obfuscated source code.

Printing and using the generated password returns a bad flag. What is happening?

The source code contains:

```
if 'aaaaaaaaaaaaaaaaaaaa' is 'aaaaaaaaaaaaaaaaaaaa':
```

This is by all means a bad syntax which the compiler is automatically translating to “==”

However, that is not what we want. There are 3 possible passwords as result: Starting with yuli, w3y or opl.

After a bit of manual testing the correct start is “w3y”.
